Reading a deployed contract at function-name level

What you read	What it is	The business step it stands for
The contract page	a contract already running on the chain	You read it without writing any code. Anyone can.
swap	one of the operations the contract offers	One asset is exchanged for another.
deposit	one of the operations the contract offers	An asset is put in.
borrow	one of the operations the contract offers	A loan is taken against what was put in.
Events	what the contract wrote out as it ran	The record of what actually happened, in order.
Its oracle dependency	information the chain cannot fetch itself	A price, or whether an event happened. If the oracle is wrong, the contract acts on false information.
A circuit breaker	one of the three common defences	A check that stops the contract when a figure looks obviously wrong.
